A network map of EMBO Members joined by shared keywords

**SAMPLE:** The map includes 1,650 EMBO Members and EMBO Associate Members who in July 2014 (i) had valid EMBO Key-words (EMBO Words) assigned to them and (ii) shared at least one of those EMBO Words with another EMBO Member.

**DISTRIBUTION:** The network parameters were adjusted to achieve a continuum of expertise rather than a strong clustering around dominant, general keywords, such as “cancer” or “development.” The 208,222 unique joins (edges) between EMBO Members (nodes) were weighted by the number of EMBO Words people shared (1 ≤ n ≤ 10). Nodes were then clustered based on this weighting (MCL-clustering) and laid out in Cytoscape 3 (Shannon et al, 2003; Allegro Edge-Repulsive Spring-Electric algorithm with a normalized linear transformation of the mclCluster parameter).

**NEIGHBOURS:** Nearest neighbours in the resulting network need not be close neighbours in expertise. It may happen that people who belong to two or more scientific communities are drawn into the centre of the network although their peers in the respective communities are clustered much farther on the outside. The final rendering was adjusted to avoid overlap between nodes and retain readability of the names.

**COLOUR CODING:** Each node was coloured with hues corresponding to the two most relevant EMBO Subject Areas for the respective EMBO Member; the centre of each node represents the primary subject area and the perimeter corresponds to the secondary subject area. The smaller circles along the periphery of the map provide a key to where people from a particular EMBO Subject Area are located.

**LIMITATIONS:** EMBO Words are mapped to individuals semi-automatically, based on free-text keywords people choose for themselves. EMBO Words are neither hierarchical nor equivalent to a concept; weighting was applied that would take into account the relative frequency of keyword terms. For the purpose of this project, EMBO did not assign keywords independently. EMBO Words are from an ontology and are neither hierarchical nor equivalent to a concept; no weighting was applied that would take into account the relative frequency of keyword terms. Individuals with fewer/longer keywords are less likely to be joined to others and end up in the periphery of the network.

**ORIGINAL USE:** On the occasion of the 50th anniversary of EMBO, the image above was printed as a circular carpet with a diameter of 4 m and displayed at the EMBO Members’ Meeting 2014.
